# From subqueries to CTEs

Ian D. Gow

19 April 2023

Take a query with subqueries and turn it into one with CTEs.

In this brief note, I use a query from Tanimura (2021) to illustrate how one can re-write a query that makes use of subqueries as a query using common table expressions (CTEs). I then show how a query written with CTEs is easily translated into a query using dbplyr. Finally, I do the analysis again from scratch, but using dbplyr expressions. In this analysis I find that the SQL query Tanimura (2021) does not quite meet the verbal specification it was intended to meet, while the dbplyr query does. I conjecture that the "building blocks" approach to SQL facilitated by dbplyr may enhance the accuracy of queries for many users.

#### 1 The data

The example query I study below comes from Chapter 4 of Tanimura (2021). The following packages will be used and should be installed.

```
library(DBI)
library(tidyverse)
library(dbplyr)
library(duckdb)
```

We first get the data, which requires an internet connection.

With the data in hand, we copy the two data tables to an in-memory DuckDB database.

#### 2 The query

Chapter 4 of Tanimura (2021) contains the following query.

```
SELECT aa.cohort_century::int as cohort_century
,round(bb.rep_and_sen_5_yrs * 1.0 / aa.reps,4) as pct_5_yrs
,round(bb.rep_and_sen_10_yrs * 1.0 / aa.reps,4) as pct_10_yrs
,round(bb.rep_and_sen_15_yrs * 1.0 / aa.reps,4) as pct_15_yrs
FROM
(
        SELECT date_part('century',a.first_term) as cohort_century
        ,count(id_bioguide) as reps
        FROM
        (
                SELECT id_bioguide, min(term_start) as first_term
                FROM legislators_terms
                WHERE term_type = 'rep'
                GROUP BY 1
        ) a
        WHERE first_term <= '2009-12-31'
        GROUP BY 1
) aa
LEFT JOIN
(
        SELECT date_part('century',b.first_term) as cohort_century
        ,count(distinct case when age(c.term_start, b.first_term) <= interval '5 years'</pre>
            then b.id_bioguide end) as rep_and_sen_5_yrs
        ,count(distinct case when age(c.term_start, b.first_term) <= interval '10 years'</pre>
            then b.id_bioguide end) as rep_and_sen_10_yrs
        ,count(distinct case when age(c.term_start, b.first_term) <= interval '15 years'</pre>
            then b.id_bioguide end) as rep_and_sen_15_yrs
        FROM
        (
                SELECT id_bioguide, min(term_start) as first_term
                FROM legislators_terms
```

Table 1: 4 records

cohort_century	pct_5_yrs	pct_10_yrs	pct_15_yrs
18	0.0502	0.0970	0.1438
19	0.0088	0.0244	0.0409
20	0.0100	0.0348	0.0478
21	0.0400	0.0764	0.0873

This query is quite complex. Can we simplify it using CTEs?

First, notice that the subqueries labelled a and b are identical. Let's clean that up. We'll put a as a CTE at the beginning of the query (after WITH) and refer to that both where we currently have it, and also in place of b. All references to b are changed to references to a. We can then run the query to check that we are still getting the same results.

```
WITH a AS (
    SELECT id_bioguide, min(term_start) as first_term
    FROM legislators_terms
    WHERE term type = 'rep'
    GROUP BY 1)
SELECT aa.cohort_century::int as cohort_century
,round(bb.rep_and_sen_5_yrs * 1.0 / aa.reps,4) as pct_5_yrs
,round(bb.rep_and_sen_10_yrs * 1.0 / aa.reps,4) as pct_10_yrs
,round(bb.rep_and_sen_15_yrs * 1.0 / aa.reps,4) as pct_15_yrs
FROM
(
        SELECT date_part('century',a.first_term) as cohort_century
        ,count(id_bioguide) as reps
        FROM a
        WHERE first_term <= '2009-12-31'
        GROUP BY 1
```

```
) aa
LEFT JOIN
(
        SELECT date_part('century', a.first_term) as cohort_century
        ,count(distinct case when age(c.term_start, a.first_term) <= interval '5 years'</pre>
            then a.id_bioguide end) as rep_and_sen_5_yrs
        ,count(distinct case when age(c.term_start, a.first_term) <= interval '10 years'</pre>
            then a.id_bioguide end) as rep_and_sen_10_yrs
        ,count(distinct case when age(c.term_start, a.first_term) <= interval '15 years'</pre>
            then a.id_bioguide end) as rep_and_sen_15_yrs
        FROM a
        JOIN legislators_terms c on a.id_bioguide = c.id_bioguide
        and c.term_type = 'sen' and c.term_start > a.first_term
        GROUP BY 1
) bb on aa.cohort_century = bb.cohort_century
ORDER BY 1;
```

Table 2: 4 records

cohort_century	pct_5_yrs	pct_10_yrs	pct_15_yrs
18	0.0502	0.0970	0.1438
19	0.0088	0.0244	0.0409
20	0.0100	0.0348	0.0478
21	0.0400	0.0764	0.0873

Next, let's do the same for aa and bb. Note that there are commas after the CTEs defining a and aa, but not after bb, as it is the last CTE before the body of the query. Again we run the query to check that we still have the same results.

```
WITH
a AS (
    SELECT id_bioguide, min(term_start) as first_term
    FROM legislators_terms
    WHERE term_type = 'rep'
    GROUP BY 1),
aa AS (
    SELECT date_part('century',a.first_term) as cohort_century,
    count(id_bioguide) as reps
```

```
FROM a
    WHERE first_term <= '2009-12-31'
    GROUP BY 1),
bb AS (
    SELECT date_part('century', a.first_term) as cohort_century,
        count(distinct case when age(c.term_start, a.first_term) <= interval '5 years'</pre>
            then a.id_bioguide end) as rep_and_sen_5_yrs,
        count(distinct case when age(c.term_start, a.first_term) <= interval '10 years'</pre>
            then a.id_bioguide end) as rep_and_sen_10_yrs,
        count(distinct case when age(c.term_start, a.first_term) <= interval '15 years'</pre>
            then a.id_bioguide end) as rep_and_sen_15_yrs
    FROM a
    JOIN legislators_terms c on a.id_bioguide = c.id_bioguide
    and c.term_type = 'sen' and c.term_start > a.first_term
    GROUP BY 1)
SELECT aa.cohort_century::int as cohort_century
,round(bb.rep_and_sen_5_yrs * 1.0 / aa.reps,4) as pct_5_yrs
,round(bb.rep_and_sen_10_yrs * 1.0 / aa.reps,4) as pct_10_yrs
,round(bb.rep_and_sen_15_yrs * 1.0 / aa.reps,4) as pct_15_yrs
FROM aa
LEFT JOIN bb on aa.cohort_century = bb.cohort_century
ORDER BY 1;
```

Table 3: 4 records

cohort_century	pct_5_yrs	pct_10_yrs	pct_15_yrs
18	0.0502	0.0970	0.1438
19	0.0088	0.0244	0.0409
20	0.0100	0.0348	0.0478
21	0.0400	0.0764	0.0873

Now we can delete the aa and bb labels and references to them. We can also tidy up the main query a little, including using the more elegant (in my view) USING syntax.

Also notice that we have age(c.term\_start, a.first\_term) three times in the query above. We can split bb into two, as we do below (now bbb followed by bb).

WITH

```
a AS (
    SELECT id_bioguide, min(term_start) as first_term
    FROM legislators_terms
    WHERE term_type = 'rep'
    GROUP BY 1),
aa AS (
    SELECT date_part('century', first_term) as cohort_century,
        count(id_bioguide) as reps
    FROM a
    WHERE first_term <= '2009-12-31'
    GROUP BY 1),
bbb AS (
    SELECT date_part('century', a.first_term) as cohort_century,
        a.id_bioguide,
        age(c.term_start, a.first_term) AS age
    FROM a
    JOIN legislators_terms c
    ON a.id_bioguide = c.id_bioguide
    AND c.term_type = 'sen' AND c.term_start > a.first_term),
bb AS (
    SELECT cohort_century,
        count(distinct case when age <= interval '5 years'</pre>
            then id_bioguide end) as rep_and_sen_5_yrs,
        count(distinct case when age <= interval '10 years'</pre>
            then id_bioguide end) as rep_and_sen_10_yrs,
        count(distinct case when age <= interval '15 years'</pre>
            then id_bioguide end) as rep_and_sen_15_yrs
    FROM bbb
    GROUP BY 1)
SELECT cohort_century as cohort_century,
    round(rep_and_sen_5_yrs * 1.0 / reps, 4) AS pct_5_yrs,
    round(rep_and_sen_10_yrs * 1.0 / reps, 4) AS pct_10_yrs,
    round(rep_and_sen_15_yrs * 1.0 / reps, 4) AS pct_15_yrs
FROM aa
LEFT JOIN bb
USING (cohort_century)
ORDER BY 1;
```

Table 4: 4 records

cohort_century	pct_5_yrs	pct_10_yrs	pct_15_yrs
18	0.0502	0.0970	0.1438
19	0.0088	0.0244	0.0409
20	0.0100	0.0348	0.0478
21	0.0400	0.0764	0.0873

We are still left with the meaningless labels (e.g., a, bb). We can give the CTEs more meaningful labels. We also clean up ages a little (e.g., USING) and move cohort\_century to first\_rep\_terms. Again we check that results are the same.

```
WITH
first_rep_terms AS (
    SELECT id_bioguide,
        min(term_start) AS first_term,
        date_part('century', min(term_start)) AS cohort_century,
    FROM legislators_terms
    WHERE term type = 'rep'
    GROUP BY 1),
cohort_sizes AS (
    SELECT cohort_century, count(id_bioguide) AS reps
    FROM first_rep_terms
    WHERE first_term <= '2009-12-31'
    GROUP BY 1),
ages AS (
    SELECT cohort_century,
        id_bioguide,
        age(term_start, first_term) AS age
    FROM first_rep_terms
    JOIN legislators_terms
    USING (id_bioguide)
    WHERE term_type = 'sen' AND term_start > first_term),
age_cuts AS (
    SELECT cohort_century,
        count(distinct case when age <= interval '5 years'</pre>
            then id_bioguide end) as rep_and_sen_5_yrs,
```

Table 5: 4 records

cohort_century	pct_5_yrs	pct_10_yrs	pct_15_yrs
18	0.0502	0.0970	0.1438
19	0.0088	0.0244	0.0409
20	0.0100	0.0348	0.0478
21	0.0400	0.0764	0.0873

Finally, let's put the "main" query in a CTE too.

```
first_rep_terms AS (
    SELECT id_bioguide,
        min(term_start) AS first_term,
        date_part('century', min(term_start)) AS cohort_century,
    FROM legislators_terms
    WHERE term_type = 'rep'
    GROUP BY 1),

cohort_sizes AS (
    SELECT cohort_century, count(id_bioguide) AS reps
    FROM first_rep_terms
    WHERE first_term <= '2009-12-31'</pre>
```

```
GROUP BY 1),
ages AS (
    SELECT cohort_century,
        id_bioguide,
        age(term_start, first_term) AS age
    FROM first_rep_terms
    JOIN legislators_terms
    USING (id_bioguide)
    WHERE term_type = 'sen' AND term_start > first_term),
age_cuts AS (
    SELECT cohort_century,
        count(distinct case when age <= interval '5 years'</pre>
            then id_bioguide end) as rep_and_sen_5_yrs,
        count(distinct case when age <= interval '10 years'</pre>
            then id_bioguide end) as rep_and_sen_10_yrs,
        count(distinct case when age <= interval '15 years'</pre>
            then id_bioguide end) as rep_and_sen_15_yrs
    FROM ages
    GROUP BY 1),
cohort_retention AS (
  SELECT cohort_century::int as cohort_century,
    round(rep_and_sen_5_yrs * 1.0 / reps, 4) AS pct_5_yrs,
    round(rep_and_sen_10_yrs * 1.0 / reps, 4) AS pct_10_yrs,
    round(rep_and_sen_15_yrs * 1.0 / reps, 4) AS pct_15_yrs
  FROM cohort_sizes
  LEFT JOIN age_cuts
  USING (cohort_century))
SELECT *
FROM cohort_retention
ORDER BY cohort_century;
```

Table 6: 4 records

cohort_century	pct_5_yrs	pct_10_yrs	pct_15_yrs
18	0.0502	0.0970	0.1438
19	0.0088	0.0244	0.0409
20	0.0100	0.0348	0.0478

cohort_century	pct_5_yrs	pct_10_yrs	pct_15_yrs
21	0.0400	0.0764	0.0873

What's the value of this last step? Well it means we can easily edit the query to debug the CTEs that are used. For example, we could put the following at then end of the query about to look into first\_rep\_terms.

```
SELECT *
FROM first_rep_terms;
```

### 3 Translating to dbplyr

Now that we have a query based on CTEs, it is *much* easier to translate to dbplyr.

```
first_rep_terms <-
    legislators_terms %>%
    filter(term_type == 'rep') %>%
    group_by(id_bioguide) %>%
    summarize(first_term = min(term_start, na.rm = TRUE),
              .groups = "drop") %>%
    mutate(cohort_century = century(first_term))
cohort_sizes <-
    first_rep_terms %>%
    filter(first_term <= '2009-12-31') %>%
    group_by(cohort_century) %>%
    summarize(reps = n())
ages <-
    first_rep_terms %>%
    inner_join(legislators_terms, by = "id_bioguide") %>%
    filter(term_type == 'sen', term_start > first_term) %>%
    mutate(age = age(term_start, first_term)) %>%
    select(cohort_century, id_bioguide, age)
age_cuts <-
    ages %>%
    mutate(id_05 = if_else(age <= years(5), id_bioguide, NA),</pre>
```

cohort_century	pct_5_yrs	pct_10_yrs	pct_15_yrs
18	0.0502	0.0970	0.1438
19	0.0088	0.0244	0.0409
20	0.0100	0.0348	0.0478
21	0.0400	0.0764	0.0873

# 4 Doing it again in dplyr

Now let's do it again more or less from scratch using dbplyr. In this version, I will build up block by block in a way that is easier (at least for me) to reason about.

For convenience, I reproduce the code we used to create first\_rep\_terms above.

Next, I produce an equivalent table for senate terms.

We are interested in [legislators] "start as representatives" as our cohort. We want to exclude those who start as senators and (to match the query in the book), we also want to exclude those who first term is after '2009–12–31'.

```
cohort_members <-
  first_rep_terms %>%
  left_join(first_sen_terms, by = "id_bioguide") %>%
  filter(first_rep_term < first_sen_term | is.na(first_sen_term)) %>%
  select(id_bioguide, first_rep_term) %>%
  mutate(cohort_century = century(first_rep_term)) %>%
  filter(first_rep_term <= '2009-12-31')</pre>
```

We can now calculate the sizes of the cohorts that we have formed.<sup>1</sup>

```
cohort_sizes <-
  cohort_members %>%
  group_by(cohort_century) %>%
  summarize(reps = n(), .groups = "drop")
```

Now let's turn to the "go on to become senators" part of our remit. This is a simple INNER JOIN with an inequality first\_rep\_term < first\_sen\_term condition. We can calculate the gap using the SQL function age().

It is easy to check that id\_bioguide is a valid key for rep\_then\_sen. This fact makes it easy to building up the curve of subsequent senate terms using a window function. Within each cohort\_century we sum up the number of rows leading up to each value of age. This

<sup>&</sup>lt;sup>1</sup>Here I am using the term "cohort" in a way that I object to below. Seems like another term is needed for precision here.

is equivalent to count(DISTINCT id\_bioguide) OVER (PARTITION BY cohort\_century ORDER BY gap), but we do not need the DISTINCT here because each value of id\_bioguide is unique here.

Note that there will be ties in terms of age here, and we deal with these using max(). That is if we had 432 representatives with gap of less than 5 years and 6 with gap of exactly 5 years, we want to step from 432 to 438 immediately.

```
rep_then_sen_gaps <-
    rep_then_sen %>%
    group_by(cohort_century) %>%
    window_order(gap) %>%
    mutate(cum_ids = cumsum(1)) %>%
    group_by(cohort_century, gap) %>%
    mutate(cum_ids = max(cum_ids, na.rm = TRUE)) %>%
    ungroup()
```

I can now combine the "start as representatives" table (cohort\_sizes) with the "go on to become senators" table (rep\_then\_sen\_gaps) to calculate the percentages by cohort\_century.

```
pct_rep_then_sen <-
    rep_then_sen_gaps %>%
    inner_join(cohort_sizes, by = "cohort_century") %>%
    mutate(pct = cum_ids/reps)
```

Rather than writing complicated CASE statements, I can make a little table in R with the three cutoff values and sent that to DuckDB and turn the rows into intervals.

Now I CROSS JOIN pct\_rep\_then\_sen and gap\_cutoffs and calculate the pct values for each before using pivot\_wider to rearrange the table to match what is shown in Tanimura (2021).

```
pct_rep_then_sen %>%
  cross_join(gap_cutoffs) %>%
  filter(gap <= cutoff) %>%
  group_by(cohort_century, cutoff) %>%
```

cohort_century	pct_5	pct_10	pct_15
18	0.0505	0.0976	0.1448
19	0.0087	0.0244	0.0407
20	0.0101	0.0349	0.0478
21	0.0109	0.0364	0.0473

But we now see different numbers. What has happened?

It turns out that there are two situations I addressed in the code that produced the table just above. First, I only included in our cohort members of Congress who *started* as representatives. The original SQL query included cohort members of Congress who had served as representatives, but who had previously served as senators (so had not *started as* representatives). Second, I was consistent in application of the first\_rep\_term <= '2009-12-31' criterion throughout. The original SQL query imposed this requirement in calculating cohort\_sizes, but not in constructing the cohorts themselves.

I would argue that the answer I produced better matches the original question from Tanimura (2021): "What share of [legislators] start as representatives and go on to become senators? (Some senators later become representatives, but that is much less common.) Since relatively few make this transition, we'll cohort legislators by the century in which they first became a representative."<sup>2</sup>

Because we have access to the underlying tables as lazy data frames in R (effectively subqueries available for use to inspect), it is easy to dig into the steps of the two queries to check our reasoning.

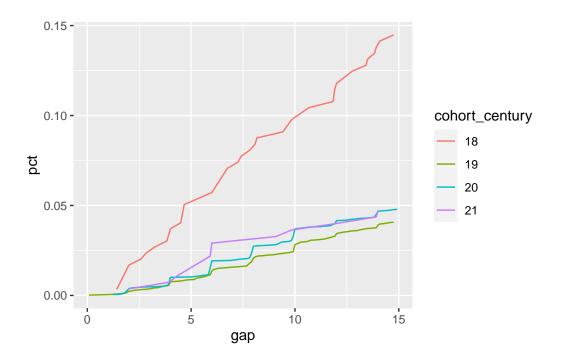

```
last_sen_terms <-
    legislators_terms %>%
    filter(term_type == 'sen') %>%
    group_by(id_bioguide) %>%
```

<sup>&</sup>lt;sup>2</sup>Minor edits here. I am not a fan of this use of the term "cohort" as the cohorts are formed based on rep\_first\_date and only aggregation of statistics happens by cohort\_century.

id_bioguide	first_rep_term	first_sen_term	last_sen_term	rep_to_sen	sen_to_rep	too_late

Because of the form of our second analysis, it is easy to make a plot.

Note that it would be easy to translate our dbplyr code—arguably a more precise solution than the original SQL query—back into SQL (probably using CTEs) if that were desired.
